Urinary Incontinence Symptoms

Urinary incontinence (symptom): Complaint of involuntary loss of urine ¹

Stress (urinary) incontinence: Complaint of involuntary loss of urine on effort or physical exertion (e.g., sporting activities), or on sneezing or coughing.
N.B.: “activity related incontinence” might be preferred in some languages to avoid confusion with psychological stress.

Urgency ² (urinary) incontinence: Complaint of involuntary loss of urine associated with urgency.

Postural (urinary) incontinence: Complaint of involuntary loss of urine associated with change of body position, for example, rising from a seated or lying position ³

6

Urinary Incontinence Symptoms

Nocturnal enuresis: Complaint of involuntary urinary loss of urine which occurs during sleep.

Mixed (urinary) incontinence: Complaint of involuntary loss of urine associated with urgency and also with effort or physical exertion or on sneezing or coughing.

Continuous (urinary) incontinence: Complaint of continuous involuntary loss of urine.

Insensible (urinary) incontinence: Complaint of urinary incontinence where the woman has been unaware of how it occurred.

Coital incontinence: Complaint of involuntary loss of urine with coitus. This symptom might be further divided into that occurring with penetration or intromission and that occurring at orgasm.

8

Bladder Storage Symptoms

Increased daytime urinary frequency: Complaint that micturition occurs more frequently during waking hours than previously deemed normal by the woman. iv

Nocturia: Complaint of interruption of sleep one or more times because of the need to micturate.3 v Each void is preceded and followed by sleep.

Urgency: Complaint of a sudden, compelling desire to pass urine which is difficult to defer.vi

Overactive bladder (OAB, Urgency) syndrome: Urinary urgency, usually accompanied by frequency and nocturia, with or without urgency urinary incontinence, in the absence of urinary tract infection (UTI) or other obvious pathology.

9

Classification of Lower Urinary Tract Symptoms (LUTS)

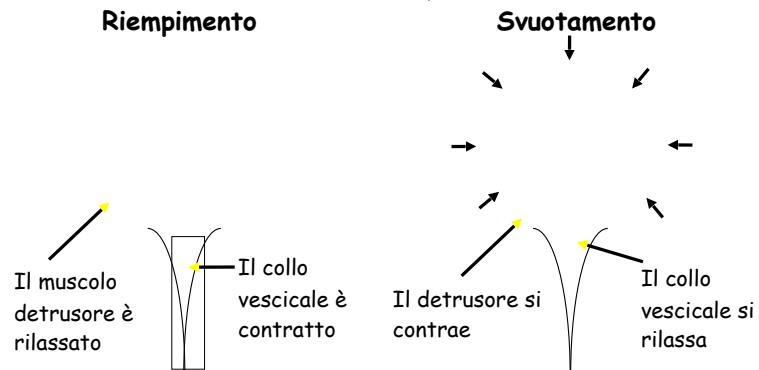

Storage	Voiding	Post-micturition
<ul style="list-style-type: none"> • Frequency • Urgency • Nocturia • Incontinence <p>Overactive Bladder</p>	<ul style="list-style-type: none"> • Slow stream • Splitting or spraying • Intermittency • Hesitancy • Straining • Terminal dribble 	<ul style="list-style-type: none"> • Post-micturition dribble • Feeling of incomplete emptying

10

Riempimento e svuotamento vescicale

Il ciclo della minzione è complesso e richiede il coordinamento del sistema vescico-sfintero-perineale

Riempimento

Svuotamento

Sensory Symptoms

A departure from normal sensation or function, experienced by the woman during bladder filling.

Normally, the individual is aware of increasing sensation with bladder filling up to a strong desire to void.

11

12

Sensory Symptoms

Increased bladder sensation: Complaint that the desire to void during bladder filling occurs earlier or is more persistent than previously experienced.
N.B.: This differs from urgency by the fact that micturition can be postponed despite the desire to void.

Reduced bladder sensation: Complaint that the definite desire to void occurs later than previously experienced despite an awareness that the bladder is filling.

Absent bladder sensation: Complaint of both the absence of the sensation of bladder filling and a definite desire to void.

13

Voiding and Postmicturition Symptoms

A departure from normal sensation or function, experienced by the woman during or following the act of micturition.

14

Voiding and Postmicturition Symptoms

Hesitancy: Complaint of a delay in initiating micturition.

Slow stream: Complaint of a urinary stream perceived as slower compared to previous performance or in comparison with others.

Intermittency: Complaint of urine flow that stops and starts on one or more occasions during voiding.

Straining to void: Complaint of the need to make an intensive effort (by abdominal straining, Valsalva or suprapubic pressure) to either initiate, maintain, or improve the urinary stream.

15

Voiding and Postmicturition Symptoms

Spraying (splitting) of urinary stream: Complaint that the urine passage is a spray or split rather than a single discrete stream.

Feeling of incomplete (bladder) emptying: Complaint that the bladder does not feel empty after micturition.

Need to immediately re-void: Complaint that further micturition is necessary soon after passing urine.

Postmicturition leakage: Complaint of a further involuntary passage of urine following the completion of micturition.

16

Voiding and Postmicturition Symptoms

Position-dependent micturition: Complaint of having to take specific positions to be able to micturate spontaneously or to improve bladder emptying, for example, leaning forwards or backwards on the toilet seat or voiding in the semi-standing position.

Dysuria: Complaint of burning or other discomfort during micturition. Discomfort may be intrinsic to the lower urinary tract or external (vulvar dysuria).

(Urinary) retention: Complaint of the inability to pass urine despite persistent effort.

Márcio Averbeck⁴  | Ryuji Sakakibara⁵  | Enrico F. Agro⁶ |
Tamara Dickinson⁷ | Christopher K. Payne⁸ | Marcus J. Drake⁹ | Bernie T. Haylen¹⁰

18

ANLUTD SYMPTOMS:

Any morbid phenomenon or departure from the normal in structure, function, or sensation, experienced by individual and indicative of disease or a health problem.

Symptoms are either volunteered by, or elicited from the individual or may be described by the patient's caregiver.

LUTS are classified as neurogenic in the presence of a relevant neurological disease ONLY. Symptoms are a subjective indicator of, or change in disease as perceived by the patient, carer, or partner that may lead the patient to seek help from healthcare professionals. They are usually qualitative. In general, LUTS cannot be used to make a definitive diagnosis. LUTS in people with neurological disease can also indicate pathologies other than NLUTD, such as urinary infection.

19

20

ANLUTD SIGNS

Any abnormality indicative of disease or a health problem, discoverable on examination of the patient. Signs are observed by the physician including simple means to verify symptoms and quantify them. Measuring the frequency, severity and impact of lower urinary tract symptoms by asking the patient to record micturitions and symptoms for a period of days provides invaluable information. The recording of "micturition events" can be in three main forms.**

Micturition Time Chart: this records only the times of micturitions, day and night, for at least 24 h.

Frequency Volume Chart (FVC): this records the volumes voided as well as the time of each micturition, day and night, for at least 24 h.

Bladder Diary: this records the times of micturitions and voided volumes, incontinence episodes, pad usage, and other information such as fluid intake, the degree of urgency, and the degree of incontinence. ††

21

Pressure Flow Study Definitions

Detrusor function during the voiding phase
in people that can initiate voluntary voiding

Normal detrusor function is a voluntarily initiated continuous detrusor contraction that leads to complete bladder emptying within a normal time span, and in the absence of obstruction. For a given detrusor contraction, magnitude of the recorded pressure rise will depend on the degree of outlet resistance.

23

Detrusor function during filling cystometry

Neurogenic detrusor overactivity is an urodynamic observation characterized by involuntary detrusor contractions during the filling phase which may be spontaneous or provoked in the setting of a clinically relevant neurologic disease. ||||

22

Pressure Flow Study Definitions

Neurogenic detrusor underactivity is defined as a contraction of reduced strength and/or duration, resulting in prolonged bladder emptying and/or a failure to achieve complete bladder emptying within a normal time span in the setting of a clinically relevant neurologic disorder.

Neurogenic acontractile detrusor is one that cannot be demonstrated to contract during urodynamic studies in the setting of a clinically relevant neurologic lesion.

24

Sphincter function during pressure flow studies

Detrusor-Sphincter Dyssynergia (DSD): describes a detrusor contraction concurrent with an involuntary contraction of the urethral and/or periurethral striated muscle. Occasionally flow may be prevented altogether.|||||

Non-relaxing urethral sphincter is characterized by a non-relaxing, obstructing urethral sphincter resulting in reduced urine flow.|||||

Delayed relaxation of the urethral sphincter is characterized by impaired and hindered relaxation of the sphincter during voiding attempt resulting in delay of urine flow.##

25

ANLUTD CLINICAL DIAGNOSES

Spinal Shock Phase is usually temporary following acute neurologic insult or SCI that is characterized by loss of sensory, motor and reflex activity below the level of injury. NLUTD in Spinal Shock: is usually a temporary complete painless urinary retention.

Suprapontine Lesion (SPL) is a neurological lesion above the pons (forebrain or midbrain). NLUTD in SPL: there is a reflex contraction of the detrusor with impaired cerebral regulation and central inhibition and usually synergistic voiding/bladder emptying***

26

ANLUTD CLINICAL DIAGNOSES

Suprasacral spinal cord/pontine lesion (SSL) is a neurological lesion in suprasacral spine and/or pons. NLUTD in SSL: Detrusor overactivity (DO) and DO incontinence are common, with or without detrusor-urethral sphincter dyssynergia (DSD), often resulting in a significant post void residual (PVR) and "high pressure" bladder.|||||

Sacral Spinal Cord Lesion (SSCL) is a neurological lesion in the sacral spinal cord. NLUTD in SSCL; findings include acontractile detrusor with or without decreased bladder compliance and usually with impaired sphincter activity.####

27

ANLUTD CLINICAL DIAGNOSES

Sacral Spinal Cord Lesion (SSCL) is a neurological lesion in the sacral spinal cord. NLUTD in SSCL; findings include acontractile detrusor with or without decreased bladder compliance and usually with impaired sphincter activity.####

Infrasacral (cauda equina and peripheral nerves) Lesion (CEPNL) is a neurological lesion affecting the cauda equina and/or peripheral nerves. NLUTD in CEPNL: acontractile detrusor and/or SUI may be present. In diabetic neuropathy, detrusor overactivity can be seen in combination with the above.\$\$\$\$

28

ANLUTD CLINICAL DIAGNOSES

Autonomic Dysreflexia is a syndrome resulting from upper thoracic or cervical spinal cord injury above T6, elicited by a stimulus in the field of distribution of the autonomous sympathetic nucleus, characterized by unregulated sympathetic function below the lesion and compensatory autonomic responses.|||||||

29

Neurogenic Overactive Bladder is characterized by urgency, with or without urgency urinary incontinence, usually with increased daytime frequency and nocturia in the setting of a clinically relevant neurologic disorder with at least partially preserved sensation.####

30

ANLUTD TREATMENTS DEFINITIONS

Bladder Reflex Triggering comprises various manoeuvres performed by the patient or the therapist to elicit reflex bladder emptying by exteroceptive stimuli (relating to, being, or activated by stimuli received from outside of the bladder).\$\$\$\$\$

Bladder Expression refers to various compression manoeuvres aimed at increasing intravesical pressure to facilitate bladder emptying with or without obvious sensation from the bladder.|||||||

Catheterization is a technique for bladder emptying employing a catheter to drain the bladder or a urinary reservoir.

Complete urinary retention is an inability to empty any amount of bladder volume (or the requirement for use of a catheter, consciously or unconsciously due to anatomical or functional bladder outlet obstruction, detrusor underactivity or both).

Incomplete urinary retention is impaired bladder emptying due to anatomical or functional bladder outlet obstruction, detrusor underactivity or both, when the voided volume is smaller than Post Void Residual.

Post void residual (PVR) is defined as the volume of urine left in the bladder at the end of micturition.⁴

31

32

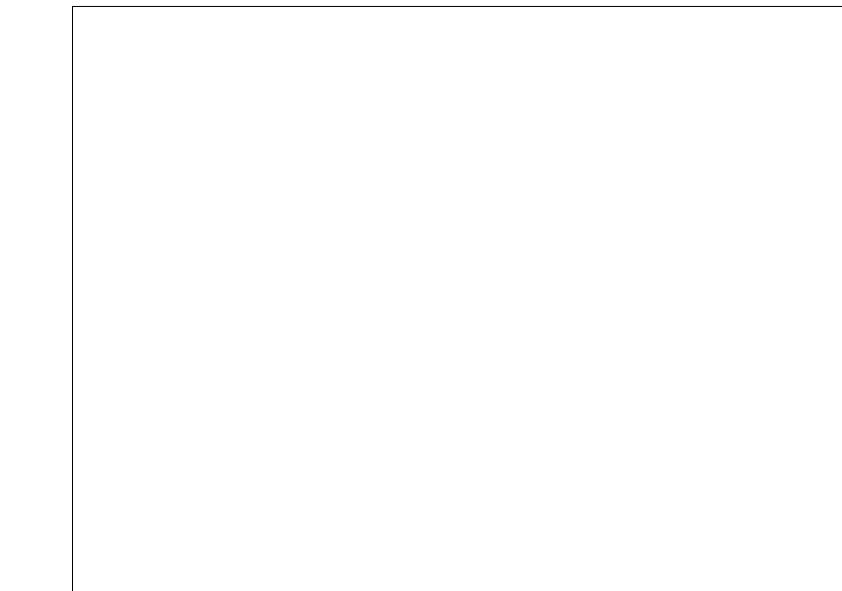

ANLUTD TREATMENTS DEFINITIONS

Intermittent Catheterization (IC) is defined as drainage of the bladder or a urinary reservoir with subsequent removal of the catheter mostly at regular intervals.

Clean IC (CIC): use of a clean technique. This implies ordinary hand and genitals washing techniques and use of disposable or cleansed reusable catheters.

No-touch technique IC: This was introduced as an easier way for the patient to perform self-intermittent catheterization with a ready-to-use catheter (pre-lubricated catheter, usually a hydrophilic catheter). A pull-in aid or special packages are used to handle the catheter without directly touching the sliding surface of the hydrophilic catheter.*****

40

41

Normal pelvic floor muscles: Pelvic floor muscles which can voluntarily and involuntarily contract and relax.

Overactive (non relaxing) pelvic floor muscles: Pelvic floor muscles which do not relax, or may even contract when relaxation is functionally needed, for example, during micturition or defaecation.

Underactive (non contracting) pelvic floor muscles: Pelvic floor muscles which cannot voluntarily contract when this is appropriate.

Non-functioning (a-functional) pelvic floor muscles: Pelvic floor muscles where there is no action palpable.

56

Vescica iperattiva

Il desiderio improvviso di urinare insorge generalmente a bassi volumi (freccia gialla)

Abrams P, Wein AJ. *The Overactive Bladder—A Widespread and Treatable Condition*. 1998.

57

Urgency Definition

Urgency is an *abnormal, or inappropriate* sudden, compelling desire to pass urine, which is *very difficult or impossible* to defer *for fear of leakage*

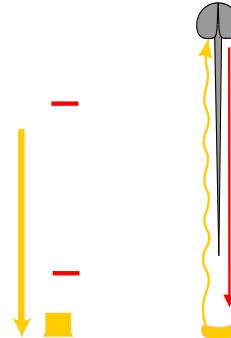

Abrams P et al. *Neurourol Urodyn*. 2006; 25: 293-294
Cardozo L et al. *BJU Int*. 2005; 95:591-596 CM-014

59

Vescica iperattiva

Il paziente è/non è in grado di inibire la minzione – può verificarsi uno svuotamento involontario (freccia rossa – segnale di attivazione)

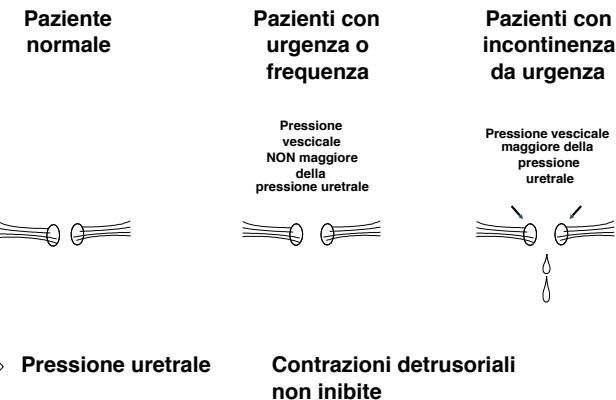

Abrams P, Wein AJ. *The Overactive Bladder—A Widespread and Treatable Condition*. 1998.

58

La sindrome da iperattività vescicale è definita dalla presenza di urgenza, con o senza incontinenza da urgenza, solitamente accompagnata dall'incremento della frequenza minzionale diurna e da nocturia, in assenza di processi settici o di altra evidente patogenesi

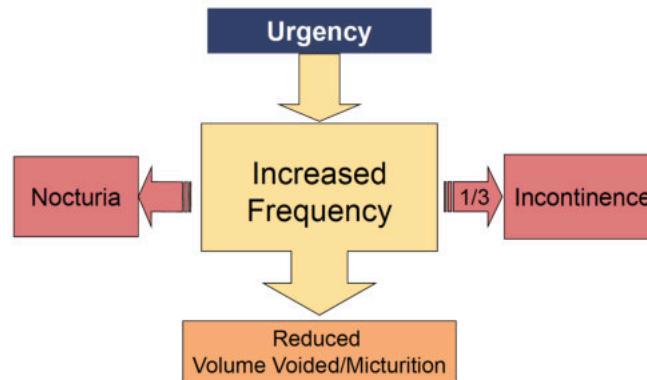

60

Vescica iperattiva: contrazioni incontrollate del muscolo vescicale

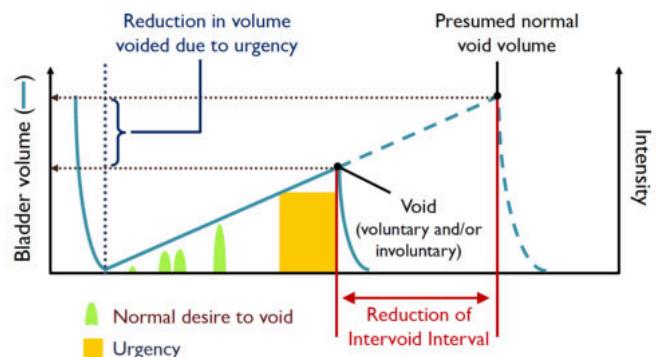

61

OAB Syndrome: A Symptomatic Sequence

62

The Micturition Cycle in OAB Effect of Urgency

63

Elemento cardine della sindrome da iperattività vescicale è quindi l'urgenza.
La fisiopatologia della sindrome da iperattività vescicale non è completamente nota ad oggi ma molto probabilmente si deve fare riferimento ad una genesi multifattoriale; si definisce sindrome da iperattività vescicale neurogena in presenza di una rilevante condizione clinica patologica neurologica.

64

Due possono essere le cause di origine dei sintomi riferibili a sindrome da iperattività vescicale:

- La ridotta capacità di elaborazione delle afferenze cerebrali
- L'incremento anomalo delle afferenze stesse a partenza vescicale e/o uretrale

65

Meccanismi di alterata elaborazione delle afferenze cerebrali

L'ipotesi neurogenica suggerisce che l'anomala elaborazione delle afferenze possa determinare un'incontinenza urinaria da urgenza. Le immagini che possono essere ottenute con la risonanza magnetica funzionale dimostrano una mancata attivazione del grigio periacqueduttale (PAG) in caso di IUU. Le donne affette da IUU manifestano una ridotta attivazione della corteccia prefrontale (PFC) ed un incremento dell'attività nella corteccia cingolata anteriore (ACC) e nell'area supplementare motoria (SMA)

67

Meccanismi di incremento anomalo delle afferenze

In questo caso sono state ipotizzate due teorie:

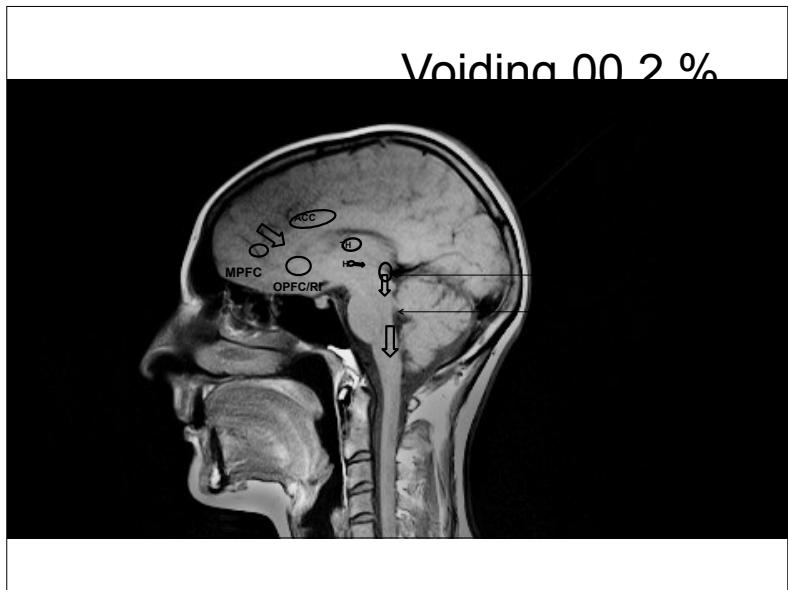

- a partenza dall'urotelio, per cui modificazioni della funzione dei recettori uoteliali ed il rilascio di neurotrasmettitori porta all'incremento di contrazioni detrusoriali involontarie

A partenza muscolare, ove modificazioni dell'eccitabilità delle fibrocellule muscolari lisce, dei miociti e/o delle cellule interstiziali determinano l'insorgenza di contrazioni non inibite

66

Lesioni delle vie centrali inibitorie o meccanismi di sensibilizzazione centrale possono facilitare la slatentizzazione di riflessi di svuotamento arcaici che possono loro volta indurre contrazioni detrusoriali involontarie e condizioni patologiche periferiche possono determinare una sensibilizzazione delle fibre C, normalmente silenti, slatentizzando un riflesso di svuotamento "C-mediato".

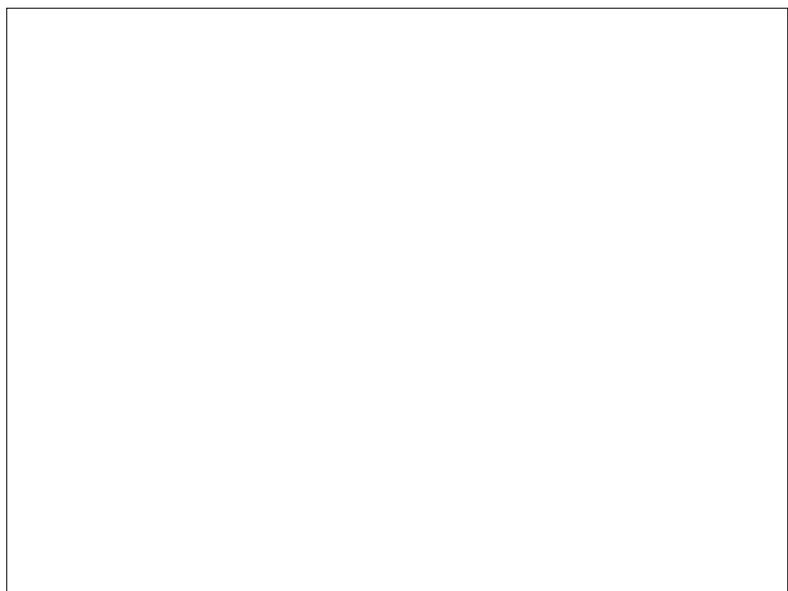

68

69

70

71

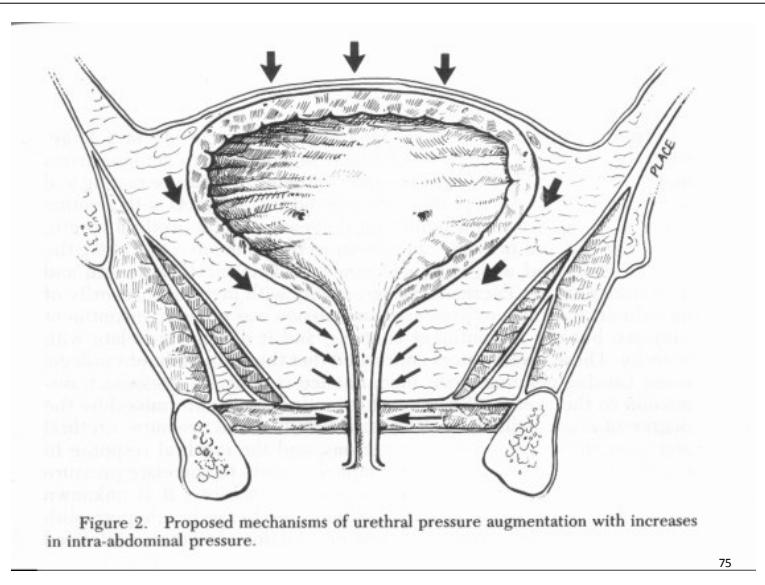

72

Le condizioni necessarie perché l'uretra possa rimanere serrata a riposo e durante gli aumenti della pressione intra-addominale sono stati ben determinati, anche se non sono ad oggi completamente chiariti le relazioni fra i diversi fattori causali. Questi ultimi sono rappresentati da:

- Un complesso sfinteriale funzionalmente valido dal punto di vista muscolare e normalmente innervato
- Un urotelio ed una sottomucosa uretrale ben vascolarizzati
- Una muscolatura liscia uretrale funzionalmente valida
- L'integrità delle strutture di sostegno vaginali

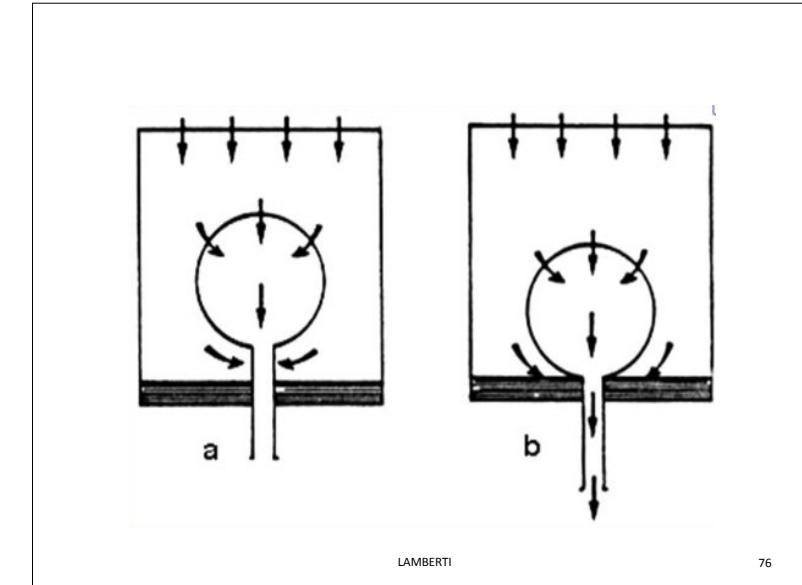

73

75

Nel passato si è data grande importanza nella patogenesi dell'incontinenza da sforzo alla modificazione del corretto posizionamento intrapelvico dei visceri.

74

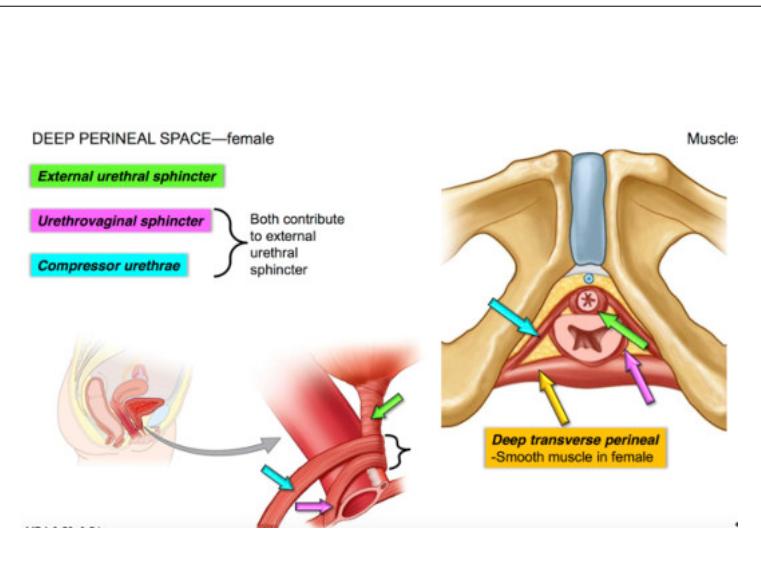

LAMBERTI

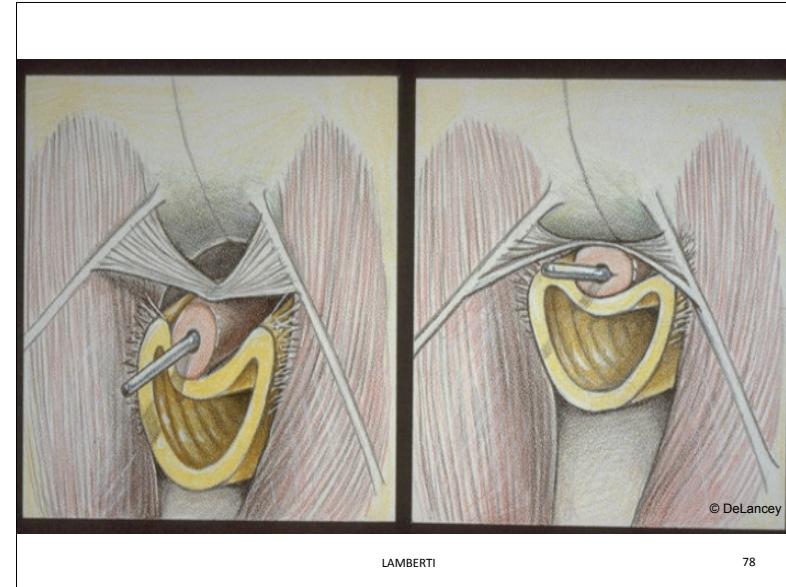

76

È stato suggerito che alla discesa dell'uretra rispetto la sua posizione intra-addominale non fosse più possibile il meccanismo di chiusura dell'uretra stessa agli aumenti di pressione. Questo concetto è ripreso come "ipotesi dell'amaca", sostituendo all'idea del solo "mantenimento" della posizione dell'uretra, l'idea del "supporto dinamico" determinato dalla contrazione della muscolatura pelvi-perineale

87

I.C.I. Parigi 2008

Mode of delivery does not seem to be a significant factor in the development of obstetric anal incontinence, i.e., AI develops after Caesarean delivery as often as after vaginal delivery (LE 2).

Obesity is perhaps the most modifiable risk factor for AI (LE 2).

As populations age, co-morbid disease becomes a significant component of fecal incontinence risk. Surgery, neurological diseases, and stroke are examples.

Cognitive and ADL impairment are associated with fecal incontinence.

three patients (47%) were lung transplanted. Forty patients (25.8%) reported FI with a mean St Mark's score of 4.9 ± 2 . Thirty-five patients (22.6%) reported UI. Eighteen patients (11.6%) reported both FI and UI. FI was significantly more frequent in older patients (34.27 vs. 29.54 years, $p = 0.03$) and in patients with associated UI ($p = 0.001$). No relationship was found between respiratory, bacterial, nutritional status, transplantation, pancreatic status, practice of physiotherapy, delivery history, and FI.

FI was reported in CF children population and seemed to be higher in males than females (12.5 vs. 4.7%).

Our results in CF adult population were sensibly higher with a FI prevalence of 25.8%.

Indeed, in the study of Faltin et al. conducted in the general population, less than 25% of patients with FI report it to their physician despite a significant impact on their quality of life.

Similarly, the other mechanisms involved in diarrhea in CF patients, such as small intestinal overgrowth, bile acid malabsorption, antibiotic action on the colonic microbiota and the fat absorption, or alteration of anal sphincter muscle tone, were not recorded due to the need for additional investigations in this young population suffering from this disabling disease. These data will be of importance in further studies. Although data on stool consistency were indirect, the prevalence of FI and its associated factors in our study mention the existence of pathophysiological mechanisms specific to cystic fibrosis patients.

The contraction force of perineal muscles seems proportional to increasing intra-abdominal pressure. This intricate reflex was altered in patients with cystic fibrosis and urinary incontinence, firstly with a delayed activation of the pelvic floor muscles, and secondly with a failure in the modulation of the contractile force depending on the intensity of coughing. Dodd et al. discussed several hypotheses to explain this dysfunction in cystic fibrosis: a quantitative and/or qualitative muscular alteration, an impairment of muscle contractility caused by pro-inflammatory cytokines, especially during acute pulmonary exacerbation, or an autonomic dysfunction can be involved in the activation of the perineal muscles. Besides, even if muscle functions are entirely preserved, pelvis floor muscles are often solicited in CF patient.

Indeed, coughing is associated with an important increase in intra-abdominal pressure, from 16.7 to 107.6 mmHg in healthy subject. In CF patient, median cough rate was 27 coughs/hour with values up to 41 coughs/hour when patients are awake. This frequent coughing associated with the high level of intra-abdominal pressure during the cough could exhaust perineal muscles and put in danger fecal continence. Thus, fecal continence is closely related to pelvic floor muscles. Their important solicitation and their dysfunction, demonstrated in urinary incontinence, could be major factors that could explain the high prevalence of FI in patients with CF

Unfortunately, the respiratory exercises based on clearance airway and training of lung function are essential in the management of cystic fibrosis. The limitation of this treatment caused by fear of urinary or fecal leakage episodes could deteriorate more precociously respiratory functions of the patient. Moreover, unlike urinary incontinence seemed to be improved after lung transplantation (69% of patients vs. 31%, respectively), the prevalence of FI was not affected by transplanting (16.7 vs. 13.5%, respectively). Irreversibility of FI and its negative impact on the chronic lung disease and the quality of life of patients need to prevent the onset of symptoms, to screen for and to treat early.

97

First degree: laceration of the vaginal epithelium or perineal skin only.

Second degree: involvement of the perineal muscles but not the anal sphincter.

Third degree: disruption of the anal sphincter muscles and this should be further subdivided into:
3a: <50% thickness of external sphincter torn.
3b: >50% thickness of external sphincter torn.
3c: internal sphincter torn also.

Fourth degree: Third degrees tear with disruption of the anal epithelium.

A meta-analysis of published reports that assessed anal sphincter integrity after vaginal delivery and correlated this with continence stated that 77%-83% (depending on parity) of anal incontinence in parous women was due to sphincter disruption.

Seventeen reports have been found eligible for inclusion in the review, encompassing 16,036 women having had 3,101 Caesarean deliveries and 12,935 vaginal births as the index event prior to anal continence assessment. None of these reports demonstrated a significant benefit of Caesarean section in the preservation of anal continence. The greater the quality of the report, the closer its Odds ratio approached 1.0. There was no difference in continence preservation in women have emergency versus elective Caesarean section.

OSTRUITA DEFECAZIONE

Per ostruita defecazione (OD) si intende un'ampia varietà di condizioni cliniche associate ad incapacità di espellere il contenuto del retto

Il disturbo è definito in modi diversi:

- Contrazione puborettale paradossa
- Disturbo all'espulsione
- Anismo
- Dissinergia del pavimento pelvico
- Sindrome del pavimento pelvico spastico
- Sindrome del puborettale spastico
- Dischezia
